WESTERN EQUINE ENCEPHALITIS – Colorado

CONTENTS

Western Equine Encephalitis	293
Epidemiologic Notes and Reports	
Infectious Hepatitis – Dover Area, New Jersey	294
International Notes – Quarantine Measures	300

The first confirmed human case of Western equine encephalitis was notified early in July (MMWR, Vol. 14, Nos. 29 and 30). Since that time through August 28, a total of 155 suspected cases has been reported. Of these, 12 have been classified on laboratory investigation as confirmed or presumptive. Table 1 lists these 12 cases on page 294. There have been two deaths in the total group, neither of which occurred among the confirmed cases. Nine of these cases occurred in Weld County where laboratory studies have been concentrated.

The suspected human cases have occurred in 16 counties but are largely concentrated in those Colorado counties east of the Rocky Mountains. The reporting of suspected cases reached a peak in the week ended August 14. Laboratory studies on these cases are in progress

By the end of July, WEE virus infection rates in *Culex tarsalis* mosquitoes had reached a level two to four times higher than that of 1964 which was in itself a year of high incidence of infection (MMWR, Vol. 14, No. 29). A WEE-like agent was also isolated from a single pool of *Aedes vexans* collected during the last week of July.

The total of cases of clinical encephalitis in horses has reached 157 through August 28. These infections have been distributed over 29 counties.

(Reported by Dr. C.S. Mollohan, Chief, Section of Epidemiology, Colorado State Department of Public Health, Disease Ecology Section, Technology Branch, CDC, Greeley, Colorado; and an EIS Officer.)

EPIDEMIOLOGIC NOTES AND REPORTS

INFECTIOUS HEPATITIS - Dover Area, New Jersey

Between February and May 1965, there were 82 confirmed cases of infectious hepatitis in the Dover area of New Jersey. The distribution of cases in time, by date of onset, is shown in Figure 1; in Table 2 the sex and age distribution of cases is listed. Figure 1 demonstrates two distinct peaks of occurrence of cases approximately one month apart with a continuation of cases through the end of April and into May. Table 2 shows that, although all age groups were affected, there was a predominance of males in the 10-14 and 15-19 age groups.

Epidemiological investigations were accordingly directed towards the dietary and shopping habits of certain religious and neighborhood groups affected and towards the preponderance of teen-age males among the patients. It emerged that 67 or 82% of the total group of patients had eaten coldcuts, purchased from a delicatessen counter in a local supermarket within a 60-day period prior to onset of illness. This, compared with the habits of 121 unaffected families otherwise randomly

Table 2

selected, indicated the delicatessen as a possible common source. During the investigation it transpired that two of the patients among the 67 were food handlers in the delicatessen. However, the onset of illness in each food handler occurred respectively during the first and second peaks of the outbreak and the food handlers could not be regarded as the initial common source of infection.

The epidemic curve, however, suggested a common primary source of infection early in February (Figure 1). Examination of the case histories of the three cases with the onset of illness on February 13 showed that they were unrelated either to the cases occurring later or to the delicatessen (Footnote to Figure 1). Those cases with dates of onset from February 21 onwards were, with 12 exceptions, all directly associated with food purchases from the delicatessen. Three of the 12 exceptions lived out of the epidemic area and 2 had history of personal contact with previous cases.

The water supply and plumbing service records of the supermarket were then examined. It was found that on February 5 the delicatessen floor area had been flooded due to a blockage in the drainage system. This blockage was traced to a sewer, into which the outflow from the supermarket toilets and the floor drainage pipe from the

delicatessen ran untrapped. The resulting backflow onto the delicatessen floor was mopped up into open buckets and the floor cleaned by the delicatessen employees.

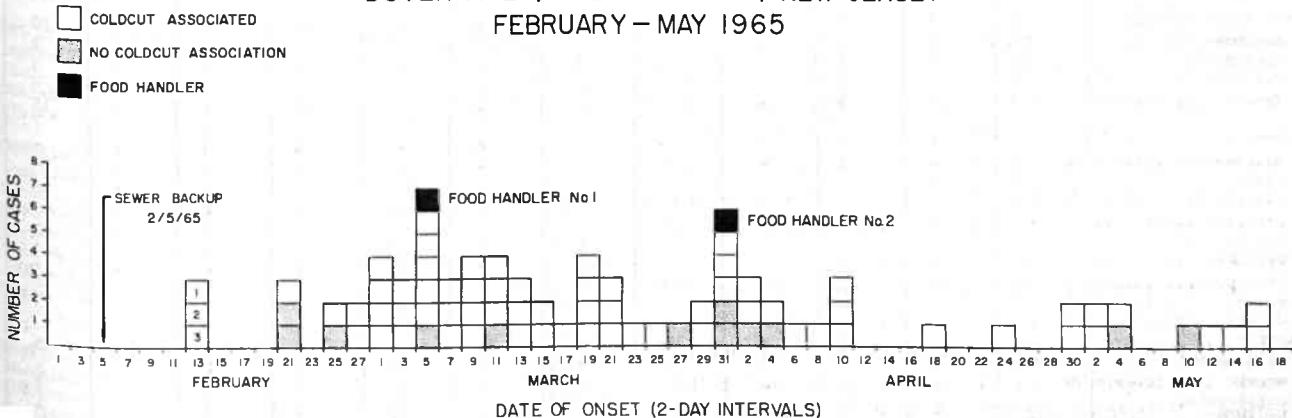

Sixteen days later the first three directly associated cases of infectious hepatitis occurred; within the next 30 days there were 48 more cases which included one of the food handlers who had been ill for 2 days before reporting sick and going off work. Twenty-five days later another wave of cases occurred, amongst whom was the second food handler. Again 30 days after this second food handler became ill, there was a final group of 13 cases.

Epidemiologic evidence suggests that this was initially a common source outbreak of infectious hepatitis which followed contamination of the delicatessen area by a backflow from an untrapped floor drain connected to a sewer. Thereafter, food handlers among the first two groups of cases may have been secondary sources of infection of foodstuffs sold at the delicatessen and so contributed to the extension and prolongation of the outbreak.

(Reported by Dr. William J. Dougherty, Director of the Division of Preventable Disease Control, New Jersey Department of Health; Mr. William J. Young, Jr., Town Health Officer, Dover, New Jersey; and an EIS Officer.)
